Abstract

1
2
3
4
5
6 Approach, avoidance, and the supervisory control system are fundamental to human
7
8 behavior. Much past research has examined the neurophysiological models relating trait
9
10 approach and avoidance. Using measures of EEG frontal asymmetry, trait approach has been
11
12 associated with greater left-frontal activity and trait avoidance has been associated with greater
13
14 right-frontal activity. However, traits related to the supervisory control system have not been
15
16 previously associated with frontal asymmetry. The current study sought to test whether trait
17
18 positive urgency, measuring the tendency towards rash action in response to extreme positive
19
20 emotional states, would relate to frontal alpha asymmetry. One hundred twenty-six individuals
21
22 completed a measure of positive urgency and resting EEG recordings. Greater positive urgency
23
24 was associated with greater relative left-frontal EEG activity. Source localization revealed that
25
26 this relationship appeared to originate from reduced right-frontal activity in the Inferior Frontal
27
28 Gyrus. These results clarify that the link between frontal asymmetry and positive urgency is
29
30 related to reduced right-frontal activity. Reduced right-frontal activity may be a potential
31
32 neurobiological trait related to the supervisory control system.

1
2
3 At the core of human functioning are three personality systems of approach, avoidance,
4 and supervisory control. Approach motivational responses have been theorized to be part of a
5 behavioral approach system (BAS; Gray, 1970, 1987; Gray & McNaughton, 2000), behavioral
6 activation system (also BAS; Fowles, 1987), behavioral facilitation system (Depue & Collins,
7 1999), and goal-approach system (Carver & Scheier 2008, Elliott 2008). In contrast, avoidance
8 motivational responses have been theorized to be part of a withdrawal or freezing system and
9 have been referred to as a behavioral inhibition system (BIS; Gray, 1970, 1987), fight-flight-
10 freeze system (FFFS; Gray and McNaughton, 2000), and threat avoidance system (Carver &
11 Scheier 2008, Elliott 2008). Essential to the approach and avoidance system is a third
12 supervisory control system theorized to generate effortful control, constraint, self-control (Carver
13 & Connor-Smith, 2010, Kochanska & Knaack 2003; Nigg 2006; Rothbart & Rueda 2005), and is
14 linked to cognitive constructs of executive control and inhibitory function (Aron, Robbins,
15 Poldrack, 2004, 2014, Hester & Garavan, 2009). Generally, the supervisory system is in place to
16 regulate both the approach and avoidance systems using effortful control to override
17 motivational impulses (Carver & Connor-Smith, 2010). This system is thought to be inversely
18 related to trait impulsivity, because trait impulsivity is strongly related to deficits in inhibitory
19 control, effortful control, and executive functions (Enticott, Ogloff, & Bradshaw, 2006; Logan,
20 Schachar, & Tannock, 1997).

40
41
42
43
44
45

46 In the past two decades, many biological models have been based on dimensions of
47 approach and avoidance (see Depue & Collins 1999, Caspi & Shiner 2006, Caspi et al. 2005,
48 Elliott & Thrash 2002, Fowles 1993, Gable & Harmon-Jones, 2010; Gray 1994, Rothbart &
49 Hwang 2005). These models propose that approach and avoidance systems are related to distinct
50 brain areas, and that individual differences in trait neural processes may reflect the sensitivity of
51
52
53
54
55
56
57
58
59
60

1
2
3 each system. For much of the past century, research has demonstrated that the left and right
4
5 frontal cortical regions are asymmetrically related to approach and avoidance motivational and
6
7 emotional (emotive) tendencies. Specifically, the left-frontal cortex is associated with emotive
8
9 processes related to approach, whereas the right-frontal cortex is associated with emotive
10
11 processes related to withdrawal (Goldstein, 1939; Rossi & Rosadini, 1967). In humans, approach
12
13 and avoidant asymmetrical activations measured by suppression of the alpha frequency band
14
15 activity during resting or baseline electroencephalographic (EEG) recordings appear as stable
16
17 traits (for reviews, see Coan & Allen, 2004; Harmon-Jones et al., 2010). Because of the strong
18
19 association between motivational direction and frontal asymmetry, frontal asymmetry has been
20
21 linked to trait measures of motivational direction using the behavioral inhibition/behavioral
22
23 activation system scales (BIS/BAS) derived by Carver and White (1994). Greater BAS is
24
25 associated with greater left-frontal activation (Amodio, Master, Yee, & Taylor, 2008;
26
27 DePascalis, Cozzuto, Capara, & Alessandri, 2013; Coan & Allen, 2003b; Harmon-Jones &
28
29 Allen, 1997; Harmon-Jones et al., 2010; Gable & Harmon-Jones, 2008; Harmon-Jones, 2006;
30
31 Harmon-Jones & Sigelman, 2001; Harmon-Jones, Peterson, & Harris, 2009), and greater BIS is
32
33 associated with greater right-frontal activation (Balconi, 2011; Balconi & Mazza, 2009;
34
35 Shackman, McMenemy, Maxwell, Greischar, & Davidson, 2009; Sutton & Davidson, 1997).
36
37
38
39
40
41
42

43 In contrast to the strong link between frontal asymmetry and approach/avoidance
44
45 systems, past research has almost entirely neglected the relationship between frontal asymmetry
46
47 and the supervisory control system. Some recent work has hypothesized that frontal asymmetry
48
49 may be associated with traits and behaviors related to the supervisory control system (Grimshaw
50
51 & Carmel, 2014). For example, greater baseline left-frontal activation is associated with trait
52
53 sensation seeking (Santesso, et al., 2008), and right-frontal theta and delta activity relate to
54
55
56
57
58
59
60

1
2
3 greater behavioral risk taking (Gianotti et al., 2009). Some work has suggested that this
4
5 asymmetric activity may relate to the right inferior frontal gyrus (for review see, Aron, Robbins,
6
7 & Poldrack, 2014). For example, the right inferior frontal gyrus has been linked with response
8
9 inhibition on a go/no-go task (Schiller, Gianotti, Nash, & Knoch, 2013) and interference of drug-
10
11 related cues in active cocaine users (Hester & Garavan, 2009). In sum, this past work suggests
12
13 that the supervisory control system may be asymmetrically related to frontal-cortical activity
14
15 (Aron, Robbins, & Poldrack, 2004; Cyders et al., 2014; Knoch et al., 2006; Peterson, Gable, &
16
17 Harmon-Jones, 2007). However, to date research has not forged a connection between trait
18
19 asymmetrical alpha activity and traits related to the supervisory system, such as impulsivity.
20
21
22
23

24
25 Research investigating the importance of trait impulsivity has begun to focus on trait
26
27 urgency, or the tendency to act impulsively during intense emotional states. Along these lines,
28
29 Cyders et al. (2007) developed the construct of positive urgency, or the tendency to act
30
31 impulsively when experiencing positive emotions. Positive emotion based urgency appears to
32
33 play a role in a number of important domains such as drinking behavior (Cyders, et al., 2010;
34
35 Cyders, Flory, Rainer, & Smith, 2009; Wray, Simons, Dvorak, & Gaher, 2012), drug use
36
37 (Zapolski, Cyders, & Smith, 2009), risky driving behaviors (Pearson, Murphy, & Doane, 2013),
38
39 and sexual aggression (Mouilso, Calhoun, & Rosenbloom, 2013). Although much past work
40
41 investigating positive urgency as a risk factor demonstrates that positive urgency is a measure of
42
43 the supervisory control system, the neurophysiological mechanisms associated with positive
44
45 urgency are unclear. Because positive urgency appears to be a stable facet of impulsivity, it is
46
47 likely related to trait neurophysiological processes such as frontal asymmetry. In addition, past
48
49 work demonstrating asymmetrical inhibitory function suggests that the pre-potent reward-based
50
51 responding as measured by positive urgency would require supervisory control to maintain long
52
53
54
55
56
57
58
59
60

1
2
3 term goals. Frontal asymmetry may serve as a biomarker of an individual's tendency towards
4 rash action. Revealing such relationships is part of a growing recognition of the importance of
5 identifying neurophysiological markers associated with personality traits.
6
7
8
9

10 In the current study we examined whether resting frontal asymmetry is related to trait
11 positive urgency, BAS, and BIS. We hypothesize that trait positive urgency will be associated
12 with an increase in relative left (vs. right) frontal activity. Consistent with past research linking
13 reduced right-frontal activity and impulsive behaviors, we hypothesize that relatively greater left-
14 frontal activity may result from a decrease in right frontal activity.
15
16

23

24 **Method**

25 **Participants and Design**

26
27
28 One hundred twenty-six (68 female, 58 male) right-handed introductory psychology
29 students participated in exchange for course credit.
30
31
32
33
34
35

36 **Procedure**

37
38
39 Participants completed the study individually. First, participants were asked to complete
40 individual difference measures of handedness, BIS/BAS, and positive urgency. Following the
41 completion of the questionnaires, EEG electrodes were applied, and resting EEG activity was
42 assessed for eight minutes. Handedness was assessed by asking participants to report which hand
43 they use to perform 13 simple behaviors (i.e., write, use a hammer, hold a match when striking
44 it). All participants were right-handed.
45
46
47
48
49
50
51
52
53

54 **Trait Positive Urgency**

1
2
3 The Positive Urgency Measure (PUM) was developed to identify the tendency to engage
4 in impulsive behaviors when in a positive mood (Cyders et al., 2007). Positive urgency is
5 measured across 14-items, such as, “I am surprised at the things I do while in a great mood”;
6
7
8 “When I get really happy about something, I tend to do things that can have bad consequences”
9
10
11 (Cyders et al., 2007, p.110). Higher PUM scores indicate greater levels of impulsive tendencies
12
13 during positive moods. Positive urgency has been identified as a component of impulsivity
14
15 independent from BAS (Cyders & Smith, 2007). Data from two participants were not included
16
17 because they failed to complete the PUM.
18
19
20
21

22 23 **Trait BIS/BAS**

24
25
26 The BIS/BAS scales contain three subscales of BAS and one scale of BIS assessed across
27
28 20 items. BIS is assessed through seven items and relates to responses in anticipation of
29
30 punishment. The following item is an example of the BIS component: “I worry about making
31
32 mistakes”. Higher BIS scores indicate greater levels of behavior inhibition. The three subscales
33
34 of BAS include: BAS Reward Responsiveness, BAS Drive, and BAS Fun-Seeking. BAS Reward
35
36 Responsiveness is assessed through five items that measure response to the anticipation of
37
38 reward. BAS Drive looks at persistent goal pursuit through four items. BAS Fun-Seeking is
39
40 comprised of four items reflecting a desire for new rewards and a willingness to approach
41
42 potential rewards. All BAS items from each subscale were averaged to obtain an overall index
43
44 score of BAS; higher BAS scores indicate greater levels of approach motivation. We report
45
46 means, standard deviations, and Cronbach’s alphas for PUM, BIS, BAS, and BAS subscales in
47
48 Table 1.
49
50
51
52
53

54 55 **EEG Assessment and Processing**

56
57
58
59
60

1
2
3 Electroencephalography (EEG) was recorded using a stretch lycra cap with 64 mounted
4 tin electrodes (Electro-Caps, Eaton, OH). EEG activity was referenced to an electrode placed on
5 the left earlobe and a ground electrode was mounted midway between FPZ and FZ. Electrode
6 impedances were under 5,000 Ω and homologous sites were within 1,000 Ω of each other.
7
8 Signals were amplified using Neuroscan SynAmps RT amplifier unit (El Paso, TX). Signals
9 were low-pass filtered at 100 Hz, high-pass filtered at 0.05 Hz, notched filtered at 60 Hz, and
10 digitized at 2,000 Hz.
11
12
13
14
15
16
17
18

19
20 Eight minutes of resting data were acquired while participants focused their gaze in front
21 of them; 4 minutes with eyes open (O) and four minutes with eyes closed (C). Two sequences
22 were used and were alternated between participants: C-O-O-C-O-C-C-O and O-C-C-O-C-O-O-
23 C. Artifacts (e.g., aberrant signals due to muscle movement or large non-blink eye movements)
24 were removed manually. Following the removal of artifacts, a regression-based eye movement
25 correction was utilized to remove blinks from the data files (Semlitsch, Anderer, Schuster, &
26 Presslich, 1986). Lastly, the data were visually inspected ensuring proper correction.
27
28
29
30
31
32
33
34
35
36
37

38 Consistent with past studies measuring trait frontal-cortical activation using alpha band
39 power (see Coan & Allen, 2004, Harmon-Jones, Gable & Peterson, 2010 for reviews), power
40 spectra epochs 1.024 s in duration were extracted through a Hamming window (50% taper of
41 distal ends). Alpha power is inversely related to regional brain activity as evidenced by
42 hemodynamic measures (Feige et al., 2005; Goldman, Stern, Engel, & Cohen, 2002; Cook,
43 O'Hara, Uijtdehaage, Mandelkern, & Leuchter, 1998) verbal tasks, (Jauk, Benedek, & Neubauer,
44 2012; Davidson, Chapman, Chapman, & Henriques, 1990), and motor tasks (Gable, Poole, &
45 Cook, 2013; Harmon-Jones, 2006). Data were re-referenced using a common average reference.
46
47 Consecutive epochs were overlapped by 50% to minimize data loss due to windowing. We
48

53
54
55
56
57
58
59
60

1
2
3 investigated the classical alpha broadband within 8 – 13 Hz (Shackman et al., 2010). Power
4 values were obtained using a fast Fourier transformation and aggregated across all resting
5 minutes. Consistent with much past work investigating frontal asymmetry (Stewart, Coan,
6 Towers, & Allen, 2011; Allen, & Cohen, 2010; Harmon-Jones, Harmon-Jones, Serra, & Gable,
7 2011), asymmetry indexes (log right minus log left) were computed for homologous sites F6/5,
8 and F8/7. Index scores were created by averaging the asymmetry indices. Because alpha power
9 is inversely related to cortical activity (Lindsley & Wicke, 1974), higher scores indicate greater
10 left hemisphere activity. These sites were aggregated to create an index of relative left frontal
11 activity. Data from five participants were not recorded due to equipment malfunction. One
12 participant was excluded because their baseline activity was greater than 3 SDs from the mean.
13
14 In order to examine whether heterogeneity in trait positive urgency, BIS, and BAS is associated
15 with individual differences in resting frontal activity, we conducted individual regression
16 analyses testing whether each self-report measure relates to the index of relative left-frontal
17 activity.

36

37 **Source Localization**

38
39
40 We utilized standardized low-resolution brain electromagnetic tomography (sLORETA)
41 to estimate the intracerebral electrical sources that generated the scalp-recorded alpha band
42 frequency activity (Pascual-Marqui, 2002). sLORETA computes electric neuronal activity as
43 current density and has been validated in comparison with fMRI, MRI, and PET (Mulert et al.,
44 2004; Vitacco, Brandeis, Pascual-Marqui, & Martin, 2002; Worrell et al., 2000; Dierks et al.,
45 2000; Pizzagalli et al., 2005; Zumsteg et al., 2006). Using the electrode positions determined by
46 the MNI 152 scalp, the subcortical areas are partitioned in 6239 voxels at 5 x 5 x 5 mm spatial
47

3 resolution. We report areas of neural activity in accordance to standard anatomical labels using
4
5 MNI space corrected to Talairach space.
6
7

8 9 **Results**

10 11 **Relationship between Frontal Activity and Positive Urgency**

12
13 We first examined whether heterogeneity in trait positive urgency can be associated with
14 individual differences in baseline frontal activity. Frontal asymmetry was positively related to
15 positive urgency, $\beta = .27$ [0.09, 0.44], $t(119) = 3.05$, $p = .003$ (See Figure 1). Individuals with
16 greater left frontal activity at baseline reported greater trait positive urgency.
17
18

19
20 Based on sLORETA statistics sub-program and visual inspection, current source density
21 analyses of the relationship between PUM scores and alpha power identified the right Inferior
22 Frontal Gyrus (MNI coordinates: X=50, Y=15, Z=0) as the origin of this relationship (See Figure
23 2). These results suggest that PUM scores relate to reduced right frontal activity at the Inferior
24 Frontal Gyrus.
25
26

27 28 **Relationship between Frontal Activity and BIS/BAS**

29
30 Next, we examined whether BIS/BAS scores were associated with individual differences
31 in resting frontal activity. The frontal asymmetry index was not correlated with BIS, $\beta = .10$ [-
32 0.08, 0.28], $t(119) = 1.10$, $p = .27$. Also, frontal asymmetry was not correlated with BAS, $\beta = -$
33 .08 [-0.26, 0.10], $t(118) = -0.88$, $p = .38$. Positive urgency remained a moderate predictor of left-
34 frontal activity when controlling for BIS, $\beta = .27$ [0.10, 0.45], $t(118) = 3.11$, $p = .002$, or BAS, β
35 = .26 [0.09, 0.44], $t(117) = 2.96$, $p = .004$. See Table 2 for the relationships between PUM, BIS,
36 and BAS. Results suggest that BIS/BAS did not relate to frontal asymmetry in the current
37 sample.

51
52
53
54
55
56
57
58
59
60

1
2
3 Our confidence intervals are a range of plausible values for the relationship between
4 positive urgency and left frontal activity. Values outside the CI are relatively implausible. The
5
6 lower bound estimate (lower limit) suggests that positive urgency remains a small predictor of
7
8 greater left frontal-cortical activity.
9
10
11

12 13 14 15 16 **Discussion**

17
18 The present study revealed that baseline frontal-cortical activity measured through frontal
19 asymmetry is associated with greater trait positive urgency. Consistent with predictions, greater
20 relative left-frontal activity related to greater trait impulsivity. Source localization of this
21 relationship revealed its origin as reduced activity in the right Inferior Frontal Gyrus. These
22 results suggest that the relationship between greater relative left-frontal activity and positive
23 urgency stem from relatively greater left-frontal activity because of deactivated right-frontal
24 activity in the Inferior Frontal Gyrus. Reduced right-frontal cortical activity suggests that the
25 supervisory control system related to trait impulsivity may relate to reduced functioning of the
26 avoidance system. Greater relative left-frontal asymmetry has predominantly been associated
27 with approach temperament and behaviors. These new findings suggest that greater relative left-
28 frontal asymmetry associated with the supervisory control system is driven by reduced right-
29 frontal activation.
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46

47 Past research suggests that reduced right frontal activity through temporary or permanent
48 lesions results in greater approach-related behaviors such as mania or aggression (Sackeim et al.,
49 1982; d'Alfonso et al., 2006). Other work suggests that right-frontal activity relates to the
50 supervisory control system, as evidenced by enhanced impulsivity (Aron, Robbins & Poldrack,
51 2014; Knoch et al., 2006). The current findings provide new insight into the link between
52
53
54
55
56
57
58
59
60

1
2
3 personality traits and neurophysiological markers. Previous research has neglected to research
4
5 the connection between asymmetric cortical activity specific to the alpha band (inverse of
6
7 cortical activity) and trait individual differences in impulsivity. This is the first instance of
8
9 research exploring the relationship of positive urgency, and baseline cortical activity.
10
11

12
13 Results from this study suggest that reduced right-frontal cortical activity may be a
14
15 neurophysiological marker of an individual's propensity towards rash action under intense
16
17 positive emotional states. Positive urgency is a unique personality construct that predicts a wide
18
19 range of risky behaviors. The current results suggest that positive urgency is related to reduced
20
21 right-frontal activity. Baseline cortical asymmetry may play a role in promoting risky behaviors.
22
23 Better understanding the neurophysiological correlates of positive urgency may contribute to our
24
25 understanding of how urgency contributes to substance use and pathologies associated with
26
27 impulsivity. For example, the neural correlates associated with positive urgency may shed light
28
29 on pathological and addictive behaviors. Future research should investigate the potentially
30
31 mediational role of frontal asymmetry in disorders and behaviors associated with positive
32
33 urgency.
34
35
36
37

38
39 The current results did not find that trait behavioral approach sensitivity related to
40
41 baseline frontal asymmetry. However, much past research demonstrates that greater left-frontal
42
43 activation evoked by approach-motivated emotional states is related to individual differences in
44
45 approach motivation (Gable & Poole, 2012, 2014; Harmon-Jones, Gable, & Peterson, 2010).
46
47 Perhaps the link between approach/avoidance systems and frontal asymmetry may be largely
48
49 driven by situational context, such as emotional/motivation states. The relationship between
50
51 individual differences in frontal asymmetry and approach/avoidance systems may be more
52
53 pronounced in the context of emotional responses (Coan, Allen, & McKnight, 2006). However,
54
55
56
57
58
59

1
2
3 because the current research found a robust association between positive urgency and baseline
4 frontal activity, the link between baseline frontal asymmetry and trait impulsivity may be less
5 influenced by situational context.
6
7
8
9

10 Of note in the current findings is that positive urgency and greater relative left-frontal
11 cortical activity have been associated with positive affect. However, it is unlikely that the current
12 results are dependent on positive mood. Past work examining greater relative left-frontal activity
13 has linked greater left-frontal activity with negative affects such as anger (see Harmon-Jones,
14 Peterson, & Gable, 2010 for review), suggesting that it is approach motivation, rather than
15 positive affect that evokes relatively greater left frontal activity. However, it is unlikely that the
16 association between greater left-frontal asymmetry and positive urgency is due to enhanced trait
17 approach motivation. In the current findings, the relationship between relative left-frontal
18 cortical activity and positive urgency was not diminished when controlling for the variance in
19 behavioral approach. Examination of the psychometric properties of PUM and BAS reveals that
20 positive urgency represents a distinct factor from those represented by the subscales of BAS
21 (Cyder et al., 2007). Indeed, the current findings support this distinction; overall, positive
22 urgency was unrelated to the BAS scales. Moreover, positive urgency, but not BAS scales,
23 related to resting frontal asymmetry. Future research is needed to more fully examine the
24 relationship between frontal asymmetry and positive urgency during affective states.

45 Investigating neurophysiological measures associated with traits related to impulsivity
46 are key to better understanding the supervisory control system mediating the approach and
47 avoidance systems. The current results help to clarify that the link between trait positive urgency
48 and greater left-frontal activity is driven by reduced right frontal activity. Because much past
49 work has associated frontal asymmetry with approach and avoidant systems, the current results
50

2
3 suggest that deficits in the supervisory control system may be related to neural substrates
4
5 associated with these motivational systems.
6
7

8 This is the first study to link the trait neurophysiological marker of resting alpha
9
10 asymmetry with trait impulsivity, as measured by positive urgency. These results suggest a
11
12 potential underlying neurobiological mechanism for the development and maintenance of trait
13
14 positive urgency. Emotion-based rash action associated with relatively greater left frontal activity
15
16 may be a means through which individuals have increased reactive approach-related tendencies
17
18 and affect. These results are in line with a growing recognition of the importance of identifying
19
20 neural or neurophysiological markers of personality traits related to core systems of human
21
22 behavior (Cyders et al., 2014; Nusslock et al., 2012). Such markers can increase understanding
23
24 of the physiology of traits and the underlying mechanisms of these systems.

For Peer Review

Table 1 – Means and SDs of PUM, BIS, and BAS

Scale	Mean (SD)	Cronbachs (α)
PUM	2.01 (0.71)	.92
BIS	2.87 (0.52)	.73
BAS	3.11 (0.35)	.81
BAS RR	3.44 (0.42)	.74
BAS DRIVE	2.79 (0.55)	.73
BAS FUN	2.98 (0.54)	.62

Note. Possible ranges for each scale are the following: for PUM, 1-5; for BIS/BAS, 1-7. Means and standard deviations (in parentheses) for PUM, BIS, and BAS scales are from the current sample. PUM = Positive Urgency Measure; BIS = Behavioral Inhibition System; BAS = Behavioral Activation System; BAS RR = Behavioral Activation System Reward Responsiveness; BAS DRIVE = Behavioral Activation System Drive; BAS FUN = Behavioral Activation Fun Seeking.

Figure 1 – Relationship Between Relatively Greater Resting Left-Frontal Activity and Positive Urgency

1
2
3
4 **Figure 2** – Current source density analyses of the correlation between positive urgency and alpha power
5
6 (less cortical activity) in the frontal cortex revealed the origin at the right Inferior Frontal Gyrus (MNI
7
8 coordinates: X=50, Y=15, Z=0). The strength of the correlation coefficient is identified by the color
9
10 scale. Red/yellow source localizations are associated with less cortical activity (greater alpha power).
